P  mandatory course/module

1. The ECTS credits assigned in the Module Catalogue are designated as follows: Credit Points not listed in parentheses are awarded when the pertinent examination of the module or module parts have/has been completed successfully. Credit Points in parentheses are listed for calculatory purposes only.

2. The semester for taking a module can either be binding or may be considered as a recommendation, depending on the applicable data in Anlage 2 of the Prüfungs- und Studienordnung for your Programme. In this Module catalogue, the options are indicated as „scheduled semester“ and „recommended semester“.

3. Please note: The Module Catalogue is merely intended to serve as an orientation whereas the provisions of the applicable version of the Prüfungs- und Studienordnung (in German only) of your Programme are legally binding. See: www.lmu.de/studienangebot and select your Programme.

Semester
Recommended semester: 1

Duration
The successful completion of the module takes 1 semester.

Content
Students familiarize themselves with an aspect of theoretical and mathematical physics and present it to their peers. They balance the importance of various aspects and choose means and media for a successful presentation. A soft skill is a competence that is not part of the scientific subject but related to it. It can for example be acquired in a language course or a programming class or a workshop on skills like scientific writing, business planning or successful job interviews.

Learning outcomes
Participants identify strategies for successful presentations and can implement them. They can get an overview on an advance scientific topic using the available literature and select the most important aspects for their presentation. They can reason about aspects of quality of a presentation and future improvements. In the soft skill, they master basic competences in a critical aspect for their future careers outside the main subjects of their study.

Type of examination
Scientific presentation

Type of assessment
The successful completion of the module will be graded.

Complusory elective module with mandatory courses

Usability of the module in other programmes
MSc Mathematik

Elective guidelines
The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements
None

Semester
Recommended semester: 1

Duration
The successful completion of the module takes 1 semester.

Content
This module treats the foundations of quantum mechanics and fundamental mathematical properties of Hamilton operators and their spectral theory. It introduces fundamental notions of mathematical quantum mechanics. It discusses principles of quantum mechanics and measurement (EPR paradox and Bell’s inequality) and mathematical foundations of unbounded and self-adjoint operators (domain of definition, graphs, adjoints, spectrum, criteria for self-adjointness, spectral theorem, quadratic forms). Then Coulomb-Schrödinger operators, the essential spectrum,
invariance under compact perturbations and the minimax principle will be presented. This is followed by elements of the theory of many-particle systems (density functional theory, second quantization, glimpses of quantum field theory) and its applications (e.g. Hartree-Fock approximation, superconductivity and superfluidity). At the end the basics of scattering theory (one-particle problems, the existence of wave operators) will be discussed.

Learning outcomes
It is the aim to convey the subjects of the module to empower students to apply them in their research projects. They understand analytical methods and can apply them to quantum mechanics.

Type of examination
Written exam or oral examination

Type of assessment
The successful completion of the module will be graded.

Requirements for the gain of ECTS credits
ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

Content

The module covers the following topics: Manifolds, vector fields and flows, Lie groups and Lie algebras, tensors and differential forms, vector bundles and connections, Riemannian metrics and curvature, model spaces of constant curvature, homogeneous spaces, Einstein manifolds. In particular, it discusses submanifolds of Euclidean space, foliations, distributions, Frobenius’ theorem, multilinear algebra, partitions of unity, orientations, integration on manifolds, Stokes’ theorem, de Rham cohomology.

## Content

- Basic Concepts of Quantum Field Theory
- Path integral representation of quantum field theory, perturbation expansion, Feynman diagrams
- From Green functions to scattering cross sections, particle states, LSZ reduction
- Renormalization, regularization, effective field theory, renormalization group, running couplings
- Symmetries and relativistic particles & quantum fields with spin, fermionic path integral, Feynman rules for general fields
- Vector fields and gauge symmetry, quantum electrodynamics

<table>

Content

The aim of this module is to learn established and modern concepts in theoretical condensed matter physics. The contents of this module vary somewhat from year to year, depending on the preferences of the lecturer; interested students are advised to contact the lecturer in advance for details. A typical module could be structured as follows: It starts with a brief recapitulation of crystal structures and classification, then addresses X-ray elastic scattering and neutron inelastic scattering and discusses static and dynamic structure factors. Next come phonons, followed by
tight-binding models (e.g. the dispersion of graphene and polyacetylene), also highlighting the consequences of inversion symmetry, time reversal symmetry, and spin-obit coupling. Next is a phenomenological discussion on semiconductors. The second half of the module is devoted to the integer quantum Hall effect, the Berry phase and the role of topology, topological insulators and the fractional quantum Hall effect. Further optional topics include Anderson localization, magnetism or BCS superconductivity. The module does not use techniques from field theory.

**Learning outcomes**

The main goal of this module is to give an overview over the many phenomena in modern condensed matter theory from a material-specific point of view. After successful completion of the module students are able to:

- understand X-ray and neutron scattering;
- understand the role of symmetry and topology in band structures;
- compute phonon and tight-binding spectra;
- explain the working of semiconductors;
- compute the Berry phase;
- understand the bulk-edge correspondence in topological materials;
- work with Laughlin wavefunctions and composite fermions;

work through advanced condensed matter physics topics on their own.

**Type of examination**

Written exam or oral examination or term paper

**Type of assessment**

The successful completion of the module will be graded.

**Requirements for the gain of ECTS credits**

ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

## Semester
Recommended semester: 1

## Duration
The successful completion of the module takes 1 semester.

## Content
The module first introduces the method of separation of variables and the Fourier method to solve initial value problems for the heat and wave equations. Then first order differential equations will be discussed. The module continues with the n-dimensional heat equation, especially with the representation of the solution, uniqueness and maximum principle. Next d’Alembert and Poisson formulas, Hadamard’s descent method, finite speed of propagation and Huygens’ principle for n-dimensional wave...
equations will be introduced. Finally, the n-dimensional Poisson equation, the Green representation formula, the mean value property of the Poisson integral formula, the maximum principle, Perron’s method and variational methods will be discussed. A number of geometric problems and numerous phenomena that are modelled in the natural science and increasingly also in economic sciences, lead to partial differential equations. The main goal of the module is to explore the existence, uniqueness and fundamental properties of the classic solutions of three main types of 2nd order partial differential equations.

| Learning outcomes | Students become familiar with basic questions and methods of partial differential equations. They are able to understand mathematical processes and see them in the framework of partial differential equations. |
| Type of examination | Written exam or oral examination |
| Type of assessment | The successful completion of the module will be graded. |
| Requirements for the gain of ECTS credits | ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully. |

The successful completion of the module takes 1 semester.

Content

The module covers the following topics: Covering spaces and singular homology theory, in particular basic notions of set theoretic topology, homotopy, fundamental group, Seifert and van Kampen’s theorem, coving theory, universal covering, classification of coverings, Hurewicz’ theorem, CW complexes, cellular homology, classical theorems of topology.

Learning outcomes

The module aims to give an introduction to the basic concepts and methods of both differential and algebraic topology.

For successful completion of the module, 9 ECTS credits have to be acquired. Class attendance averages about 6 contact hours. Including time for self-study, 270 hours have to be invested.

Module type
Complussory elective module with mandatory courses

Usability of the module in other programmes
MSc Physics

Elective guidelines
The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements
None

Semester
Recommended semester: 1

Duration
The successful completion of the module takes 1 semester.

Content
This module gives an introduction into the theory of closed strings (Nambu-Goto action, Polyakov action) in terms of a two-dimensional conformal field theory. It describes the various approaches to quantization and introduces compactifications on tori. Later, the discussion is extended to open strings and D-branes and the relation between string theory and its low energy description in terms of an effective field theory is developed. It gives an outlook to modern topics in target space like dualities, M-Theory, AdS/CFT correspondence.

Content

The course covers the following topics: Gibbs measures: DLR conditions, existence, uniqueness (Dobrushin's theorem), phase transitions, absence of spontaneous symmetry breaking in two dimensions. Ising model: high temperature phase, Peierls argument, cluster expansion, Fortuin-Kasteleyn representation, FKG inequality, spontaneous symmetry breaking in continuous models. Non-equilibrium model systems: Exclusion processes, matrix product ansatz, interacting particle systems. The main goal of this course is to acquire a deeper mathematical and physical understanding.
of phase transitions and collective phenomena that occur in macroscopic interacting particle systems.

Content
This module covers the following topics: Electrical conductance as scattering problem and conductance quantization, quantum Hall effect, quantum dots as “artificial atoms”, tunneling, Coulomb blockade and single electron transistor, disorder effects (random matrix theory and weak localization), shot noise and full counting statistics of electronic transport, dephasing and partially coherent transport, mesoscopic superconductivity (e.g. Josephson arrays and qubits), interacting electrons in one dimension (“Luttinger liquid”), spin effects (e.g. spin-orbit scattering and Kondo effect), relation to quantum optics and the physics of
ultracold atoms. This module offers an introduction to one of the central modern areas of theoretical condensed matter physics.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements

None

Semester

Recommended semester: 2

Duration

The successful completion of the module takes 1 semester.

Content

The aim of this module is to learn basic methods of modern quantum many-body theory and to apply them to various problems in condensed matter physics. The contents of this module vary somewhat from year to year, depending on the preferences of the lecturer; interested students are advised to contact the lecturer in advance for details. A typical module could be structured as follows: It starts with an introduction to second quantization and its application to paradigmatic models of interacting electrons, such as the Hubbard- and Heisenberg models, the Bogoliubov theory of weakly interacting bosons, Hartree-Fock mean-field theory and the
Bardeen-Cooper-Schrieffer (BCS) theory of superconductivity. The subsequent, main part of this module develops functional integral techniques for bosons and fermions in the finite-temperature Matsubara formalism, discusses Green’s functions and their analytic properties, and introduces perturbation theory using Feynman diagrams and elementary non-perturbative methods such as the Hubbard-Stratonovich transformation. These methods are then used to study properties of interacting electron systems (random-phase approximation, screening and plasmon excitations) and to discuss Fermi liquid theory. The next chapter covers the linear response formalism (Kubo formula) as the central tool to establish a connection between theoretically computable correlation functions and experimental observables. The final core topic is an extended discussion of the BCS theory of superconductivity, starting from the functional integral representation.

Learning outcomes

After completing the Module the student is able to:

- Understand and apply the formalism of second quantization to study interacting quantum many-particle systems.
- Explain the main ideas behind common approximation schemes, in particular mean-field theory and the Bogoliubov transformation.
- Understand the functional integral representation of partition functions, manipulate functional integrals, and apply a Hubbard-Stratonovich decoupling.
- Explain the properties of Green’s functions and their use in diagrammatic perturbation theory.
- Understand and use the linear response formalism to compute experimental observables of interacting many-particle systems.
- Understand the theory of BCS superconductivity.
- Follow current research topics and use the toolbox of many-body methods to start independent research.

Type of examination

Written exam or oral examination or term paper

Type of assessment

The successful completion of the module will be graded.

Requirements for the gain of ECTS credits

ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

Responsible contact

Prof. Dr. Jan von Delft

Language(s)

English

For successful completion of the module, 9 ECTS credits have to be acquired. Class attendance averages about 6 contact hours. Including time for self-study, 270 hours have to be invested.

Module type
Complusory elective module with mandatory courses

Usability of the module in other programmes
MSc Physics

Elective guidelines
The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements
None

Semester
Recommended semester: 2

Duration
The successful completion of the module takes 1 semester.

Content
The following systems will be considered: trapped ions, neutral atoms in magnetic and optical traps, thermal ensembles of atoms and photons. Applications in the field of quantum information processing as well as in Bose-Einstein condensation will also be described. Quantum optics deals with the interaction of light and matter (atoms and molecules). During the last few years, this topic has acquired a renewed interest through the experimental achievements made in atomic physics, and the possibility of controlling and manipulating atomic quantum states.
using light. This module will review the theoretical techniques used to describe the interactions of light with atoms, as well as the physical phenomena observed in actual experiments dealing with cold atoms.

Semester
Recommended semester: 2

Duration
The successful completion of the module takes 1 semester.

Content
This module offers an overview on advanced chapters of mathematical quantum mechanics. First semiclassical approximations, WKB-calculus, pseudodifferential operators and the Wigner formalism will be discussed. Then basic properties of periodic quantum systems will be presented, among others, the Bloch decomposition, eigenvalues and eigenfunctions of one-body Schrödinger operators and asymptotic eigenvalue statistics as well as mathematical
descriptions of classical and quantized magnetic fields. Next the static problems of many body systems (theory of large atoms for fermionic systems and Bose-Einstein condensation for bosonic systems) will be presented, followed by the dynamical problems of many body systems (scattering theory, asymptotic completeness, correlation functions, BBGKY-hierarchy). At the end, disordered quantum systems and Anderson-localization will be discussed.

### Learning outcomes

The main goal of this module is to offer an overview of the most successful current research directions for quantum problems that can be tackled by rigorous mathematical methods.

### Type of examination

Written exam or oral examination

### Type of assessment

The successful completion of the module will be graded.

### Requirements for the gain of ECTS credits

Semester
Recommended semester: 2

Duration
The successful completion of the module takes 1 semester.

Content
The module introduces the following subjects: First order partial differential equations (method of characteristics, Hamilton’s equations, Hamilton-Jacobi equation); Fourier transform (Schwartz space, distributions, Sobolev spaces, weak solutions); Second order linear partial differential equations (wave equation, diffusion equation, method of stationary phase and Maxwell equations, geometric optics, Schrödinger equation, inverse problems);
nonlinear equations (minimal surfaces, variational methods, Monge-Ampere equation, reaction-diffusion equations, Stefan problems, Euler and Navier-Stokes equations, nonlinear heat and Schrödinger equation, Einstein equation). The module develops modern mathematical tools and applies them to the most important partial differential equations that have a direct physical origin.

<table>

Recommended semester: 2

### Duration

The successful completion of the module takes 1 semester.

### Content

This module introduces the fundamental properties of Supersymmetry. It covers supersymmetric quantum mechanics, SUSY algebra and its representations, supersymmetric field theories and superfield formalism, supersymmetric gauge theories. It explains the special features of supersymmetric theories compared to ordinary theories. This includes a discussion of the Witten index in SUSY quantum mechanics, path integral localization in SUSY QM, as well as applications in quantum field theories, such as non-renormalization arguments, role of BPS sectors, Seiberg-Witten theory.
**Learning outcomes**

After successful completion of this course the students are able to: 1. State basic definitions: Lie algebra, graded Lie algebra, vector space, graded vector space, representation. 2. Construct spinor representations and (extended) SUSY algebras 3. Construct supersymmetric Lagrangians 4. Compute the Witten index in SUSY QM, explain its invariance under deformations. 5. Compute path integrals in simple SUSY QM models. 6. Compute classical moduli spaces of SUSY gauge theories.

**Type of examination**

Written exam or oral examination or term paper

For successful completion of the module, 9 ECTS credits have to be acquired. Class attendance averages about 6 contact hours. Including time for self-study, 270 hours have to be invested.

Module type | Compulsory elective module with mandatory courses
---|---

Usability of the module in other programmes | None

Elective guidelines | The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements | None

Semester | Recommended semester: 2

Duration | The successful completion of the module takes 1 semester.

Content | The aim of this module is to provide mathematical methods needed to describe symmetries in physics. For illustration, we will also discuss physical applications. The module starts with a hands-on discussion of finite groups and their representations. We introduce and define basic concepts (groups, representations, reducible/irreducible,…), provide proofs of elementary theorems (Schur’s lemma, Maschke’s theorem) and introduce techniques in representation theory (in particular, how to decompose a representation into irreducibles). In the second part, we discuss Lie groups and their representations,
focussing on Matrix Lie groups, and state theorems such as the Peter-Weyl theorem and Schur-Weyl duality. We emphasize similarities between compact Lie groups and finite groups. The third part of the course discusses Lie algebras, focussing mainly on semi-simple complex Lie algebras. We discuss and explain their structure, partially include proofs, ending up with the classification theorem. Basics of the representation theory will also be covered. Physics applications covered in the module include selection rules for molecules, crystal field splitting, as well as the symmetry of hadrons.

Learning outcomes
After successful completion of the module the students are able to:

- State basic mathematical definitions: group, algebra, Lie algebra, representation.
- Understand the natural structure preserving maps between these concepts.
- Decompose representations of finite groups into irreducible ones using the character table.
- Associate a Dynkin diagram to a complex semi-simple Lie algebra.
- Read off a complex semi-simple Lie algebra from a Dynkin diagram.
- Understand the meaning and importance of theorems on compact Lie groups (Peter-Weyl-theorem, Schur-Weyl duality).
- Apply group theory to quantum mechanical systems.

Type of examination
Written exam or oral examination

Type of assessment
The successful completion of the module will be graded.

Requirements for the gain of ECTS credits
ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

### Semester

Recommended semester: 2

### Duration

The successful completion of the module takes 1 semester.

### Content

The module begins by developing important concepts such as D-branes, supersymmetric compactifications on orientifolds, orbifolds and Calabi-Yau spaces. Further topics are the computation of string amplitudes (tree-level, 1-loop, automorphic functions), string dualities (M-theory, S-duality, mirror symmetry) and extra dimensions.

### Learning outcomes

The main goals of this module are to master perturbative superstring theory and to understand basic non-perturbative properties.

</tbody>
</table>

For successful completion of the module, 9 ECTS credits have to be acquired. Class attendance averages about 6 contact hours. Including time for self-study, 270 hours have to be invested.

Module type

Compulsory elective module with mandatory courses

Usability of the module in other programmes

MSc Physics

Elective guidelines

The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements

None

Semester

Recommended semester: 2

Duration

The successful completion of the module takes 1 semester.

Content

After an introduction of the mathematical concepts (topological charge, solitons), the basic examples non-perturbative classical solutions in various dimensions like monopoles (Dirac, t’Hooft-Polyakov) and instantons are discussed. Then their role in quantized theories is highlighted, in particular for symmetry breaking, anomalies and CP-violation. In the following, the properties of solitons and instantons in supersymmetric theories (BPS states) are treated.

Learning outcomes

Students can reason about field theories beyond perturbation theory. They can successfully apply notions from topology to classical and quantum theories.

Entry requirements

None

Semester

Recommended semester: 2

Duration

The successful completion of the module takes 1 semester.

Content

The course derives classical black hole solutions (Schwarzschild, Reissner-Nordström, Kerr and their higher dimensional generalizations) and discusses their conformal structure. Global techniques are presented and used to discuss singularity theorems and black hole thermodynamics.

Learning outcomes

Students are familiar with axisymmetric and stationary solutions to Einstein’s equations and their physical properties. They can derive Penrose diagrams and use them to argue about global structure of a space-time solution. They have mastered the basic notions about global
techniques and how they can be used to obtain singularity theorems. They can reason about black holes as thermodynamic objects.

Compulsory elective module with mandatory courses

Usability of the module in other programmes

MSc Physics

Elective guidelines

The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements

None

Semester

Recommended semester: 2

Duration

The successful completion of the module takes 1 semester.

Content

This module treats current research topics in the fields of String Theory and Geometry.

Learning outcomes

The module aims to convey advanced methods and knowledge in a selected area of String Theory and Geometry.

Content

This module covers selected topics of a chapter in theoretical and mathematical physics. A special focus is on recent developments in these areas. After initial guidance, participants independently investigate their subject and find appropriate literature. They select the most relevant aspects and present those to their peers.

Learning outcomes

Participants are able to independently understand an advanced topic so far unknown to them. They can present their learnings to a group in a concise manner and choose the appropriate means to this end. They can identify and apply criteria for good presentations.

Type of examination

Scientific protocol

Type of assessment

The successful completion of the module will be graded.

Requirements for the gain of ECTS credits

ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

Content
This module develops advanced methods to study interacting quantum many-particle systems in and out of equilibrium. The contents of this module vary somewhat from year to year, depending on the preferences of the lecturer; interested students are advised to contact the lecturer in advance for details. A typical module could be structured as follows: It starts with a short recapitulation of field theoretical fundamentals, in particular functional integral techniques. The next part of the module introduces the renormalization group as a central tool for understanding.
effective low-energy properties of interacting quantum many-particle systems. Topics include scaling, perturbative renormalization, RG flows and fixed points, as well as the Kondo effect and the superfluid-Mott insulator transition as examples. The module then covers fundamentals of low-dimensional systems (Luttinger liquids, bosonization) and the Keldysh technique to study many-particle systems out of equilibrium. Final topics include instantons and non-perturbative techniques as well as optional topics, such as the quantum Hall effect (integer and fractional), Chern-Simons theory, disorder in many-particle systems, high-Tc superconductivity and quantum phase transitions.

Content
Quantum Information offers an introduction to the theoretical foundations of Quantum Science and Technology. The course starts with a brief motivation and an introduction to fundamental concepts and the basic formalism (pure/mixed states, evolution, completely positive maps, measurements Schmidt decomposition, tomography, quantum estimation, hypothesis testing). Then the concept of entanglement is discussed in detail, including the distinction between pure and mixed-state entanglement, entanglement entropy, quantification and conversion. Subsequently, some of the
revolutionary promises of exploiting entanglement are presented, including dense coding, quantum teleportation and quantum cryptography. Next the Bell inequalities, characterizing the quantum weirdness of entanglement and non-locality, are introduced and discussed in detail. Subsequent chapters cover central applications of quantum information theory: quantum computation, quantum algorithms such as those of Deutsch, Shor and Grover, quantum simulation, and quantum metrology. Final core topics are decoherence, Lindbladian descriptions thereof, and error correction schemes to counteract the consequences of decoherence and protect fragile quantum information. The module will typically also include one or more optional topics, such as many-body entanglement, topological quantum computation, quantum complexity, or tensor networks, which link quantum information theory to many-body physics.

**Learning outcomes**

After participation in the Module the student is able to:

- Explain fundamental concepts such as the distinction between pure and mixed states, quantum evolution, completely positive maps, and quantum measurements.
- Explain and quantify the notion of entanglement in various contexts (pure states, mixed states, purification, Bell inequalities).
- Understand and explain central applications of quantum information theory, such as quantum cryptography, quantum computation, quantum simulation, and quantum metrology.
- Understand the central ideas underlying different quantum algorithms.
- Understand the notion and the consequences of decoherence, model it using Lindbladians, and explain central elementary error correction strategies.
- Competently perform quantum mechanical computations relevant for the above topics.

**Exercise type**

Written exam or oral examination or term paper

**Type of assessment**

The successful completion of the module will be graded.

**Requirements for the gain of ECTS credits**

ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

Semester
Recommended semester: 3

Duration
The successful completion of the module takes 1 semester.

Content
This module deals with Conformal Field Theory in two dimensions, a perfect pedagogical example of Mathematical Physics with applications in String Theory and Statistical Physics. It starts with the basics, which is the underlying Virasoro algebra, its representation theory and the basic notions in CFT like the operator product expansion, fusion rules, Kac-Moody and chiral algebras. Putting the CFT on a torus reveals non-chiral aspects of CFT like partition functions, its modular properties and the Verlinde formula. Basic notions of supersymmetric CFTs are also discussed,
like the chiral ring and the spectral flow which are important for string theoretic applications. The final topic is Boundary CFT which includes the introduction of boundary states and the Cardy formula.

**Learning outcomes**
The main goal of this module is to make the students acquainted with a prime example of Mathematical physics which beautifully combines the physics of quantum field theory (QFT) with advanced mathematical structures, in effect making the theory exactly solvable and going way beyond the usual perturbative approach to QFT. Moreover, it complements the parallel course on String Theory I.

**Type of examination**
Written exam or oral examination

**Type of assessment**
The successful completion of the module will be graded.

**Requirements for the gain of ECTS credits**
ECTS credits will be granted when the module examination (or the examination of pertinent mandatory and potential elective compulsory module parts) has/have been completed successfully.

For successful completion of the module, 9 ECTS credits have to be acquired. Class attendance averages about 6 contact hours. Including time for self-study, 270 hours have to be invested.

Module type
Complusory elective module with mandatory courses

Usability of the module in other programmes
None

Elective guidelines
The module can be selected in compliance with the following rules:

From the compulsory elective modules WP 1 to WP 58, compulsory elective modules with a total of 69 ECTS credits must be selected. At least two compulsory elective modules must be selected from the compulsory elective modules WP 1 to WP 3 and WP 17.

In the 1st semester compulsory elective modules with a total of 24 ECTS credits are to be selected, in the 2nd semester compulsory elective modules with a total of 30 ECTS credits and in the 3rd semester compulsory elective modules with a total of 15 ECTS credits.

Entry requirements
MSc Mathematik

Semester
Recommended semester: 3

Duration
The successful completion of the module takes 1 semester.

Content
The module covers the mathematical description and analysis of complex random phenomena. In particular, it discusses the following topics: Weak convergence, compactness criteria, Markov processes: recurrence and transience, harmonic functions, stationary processes, ergodic theorem for Markov chains, stochastic processes in continuous time: renewal processes, Poisson process, Levy processes, Brownian motion, Donsker’s invariance principle, Martingales and stopping times in continuous time,
stochastic integral with Brownian motion as integrator, Ito formula.
